Simulate mutations in a single sequence														-
Simulate mutations in a lineage tree		 												4

SHazaM provides two functions for simulating mutated sequences, one at the sequence level (shmulateSeq), and the other at the lineage level (shmulateTree).

Both functions rely on a 5-mer targeting model for computing the probabilities of mutations at each position along the input sequence. The 5-mer targeting models currently availbale in SHazaM are:

- HH S5F: Human Heavy chain, Silent, 5-mer, Functional targeting model
- HKL\_S5F: Human Kappa and Lambda light chain, Silent, 5-mer, Functional targeting model
- MK\_RS5NF: Mouse Kappa light chain, Replacement and Silent, 5-mer, Non-Functional targeting model
- U5N: Uniform 5-mer Null targeting model

## Simulate mutations in a single sequence

shmulateSeq generates random mutations in an input sequence. This sequence is provided by the user as a string, with the acceptable alphabet being {A, T, G, C, N, .}. Note that - is not accepted as part of the input sequence. If the input sequence has a non-triplet overhang at the end, it will be trimmed to the last codon. For example, ATGCATGC will be trimmed to ATGCAT before mutations are introduced.

The total number of mutations to be introduced is user-specified. Mutations are not introduced to positions in the input sequence that contain . or N.

Mutations are introduced iteratively using a targeting model. Targeting probabilities at each position are updated after each iteration.

#### library(shazam)

```
# Input sequence
sequence <- "NGATCTGACGACACGGCCGTGTATTACTGTGCGAGAGATA.TTTA"

# Simulate introduction of 6 mutations using the default HH_S5F targeting model
shmulateSeq(sequence, numMutations=6)

## [1] "NGATTTGACGACACGGCCGAGTATTACTGTCCGATAGATT.TTTC"

# Simulate introduction of 4 mutations using the MK_RS5NF targeting model
shmulateSeq(sequence, numMutations=4, targetingModel=MK_RS5NF)

## [1] "NGATCTGACGACACGGCCATATATTATTGTGCGAGAAATA.TTTA"</pre>
```

## Simulate mutations in a lineage tree

shmulateTree generates a set of simulated sequences based on an input sequence and a lineage tree. The input sequence will act as the most recent common ancestor (MRCA) of the lineage tree, and sequences in the offspring nodes will be simulated with the numbers of mutations corresponding to the edge weights of the tree.

The lineage tree is supplied by the user as an igraph object, such as that returned by buildPhylipLineage of the alakazam package. For details, see the Reconstruction of Ig lineage trees vignette of alakazam. It is assumed that the name vertex attribute of the root node is Germline, as is the case with the trees built by buildPhylipLineage.

```
library(alakazam)
library(shazam)
library(igraph)

# Load example lineage
data(ExampleTrees, package="alakazam")
graph <- ExampleTrees[[17]]

# Input sequence to be used as MRCA of the lineage tree
sequence <- "NGATCTGACGACACGGCCGTGTATTACTGTGCGAGAGATAGTTTA"</pre>
```

# # Simulate using the default HH\_S5F targeting model shmulateTree(sequence, graph)

```

## 8 GN5SHBT06IXJIH NGACCTGACGACACGGCCGTGTATTACTGCGCGAGAGATAGTTTG
```

It is possible to exclude certain specified nodes from being considered as the MRCA and from being included as part of the simulation. To specify such nodes, use the field argument to indicate which annotation field in vertex\_attr(graph) contains information relevant to deciding which nodes to exclude, and the exclude argument to indicate the value in the annotation field that nodes to be excluded carry.

Note that when excluding some nodes, additional nodes that have not been explicitly specified by the user to be excluded may also get excluded. For example, suppose that node B is an offspring of node A; and node A has been specified by the user to be excluded. As a corollary of node A being excluded, its offspring node B will also become excluded, despite not being specified explicitly.

```
# The annotation field called "SAMPLE"
vertex_attr(graph)$SAMPLE
## [1] NA "+7d" "+7d" NA "+7d" "+7d" "+7d" "+7d" "+7d"
```

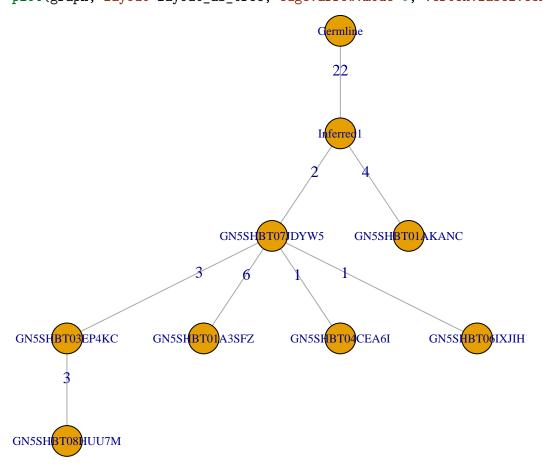

```
# notice that node "GN5SHBT01AKANC" is an offspring of "Inferred1"
par(mar=c(0, 0, 0, 0) + 0.1)
plot(graph, layout=layout_as_tree, edge.arrow.mode=0, vertex.label.cex=0.75)

```

It is also possible to add a proportional number of mutations to the immediate offsprings of the MRCA based on the fraction of the nucleotide sequence that is within the junction region. This is achieved via the optional junctionWeight argument, to be supplied as a numeric value between 0 and 1.

As an exmample, suppose that the MRCA has two immediate offsprings, each containing 2 and 4 mu-

tations respectively compared to the MRCA. With junctionWeight=0.2, the number of mutations to be introduced to these two offsprings will become round(2\*(1+0.2)) (2) and round(4\*(1+0.2)) (5) respectively.

# The "Inferred1" node is taken to be the MRCA and has 2 immediate offsprings
par(mar=c(0, 0, 0, 0) + 0.1)
plot(graph, layout=layout\_as\_tree, edge.arrow.mode=0, vertex.label.cex=0.75)

# Add 20% mutation rate to the immediate offsprings of the MRCA shmulateTree(sequence, graph, junctionWeight=0.2)
